Osmosis (/ ɒˈzˌmɒsɪs /) is the spontaneous net movement of solvent molecules through a selectively permeable membrane into a region of higher solute concentration, in the direction that tends to equalize the solute concentrations on the two sides. It may also be used to describe a physical process in which any solvent moves across a selectively permeable membrane (permeable to the ...

Porosity and permeability are two distinct physical properties of solids. Porosity refers to the extent to which tiny pores or spaces exist within the solid.

The natural moisturizing factor (NMF) is a group of hygroscopic molecules that is naturally present in skin and protects from severe drying. Glycerol and urea are two examples of NMF components that are also used in skin care applications.

Glycerol and urea can be used to increase skin

Forward osmosis (FO) is an osmotic process that, like reverse osmosis (RO), uses a semi-permeable membrane to effect separation of water from dissolved solutes. The driving force for this separation is an osmotic pressure gradient, such that a "draw" solution of high concentration (relative to that of the feed solution), is used to induce a net flow of water through the membrane into the draw ...

Desalination is a method for producing water for human consumption, irrigation or industrial utilisation. In this study, a reverse osmosis (RO) system for brackish water desalination was theoretically investigated to produce both potable drinking and agricultural water with a lower overall and specific energy consumption.

Andreone et al. revealed a key mechanism that explains how the suppression of transcytosis occurs to control BBB permeability. They discovered a single pathway revealing that the lipids transported by Mfsd2a control the formation of caveolae and therefore BBB integrity.
